ABSTRACT
The present study seeks to ascertain the capacity of aqueous extract of N. tabacum alter and interfere with polymerization of deoxygenated sickle cell haemoglobin (deoxyHbS) molecules in vitro. Spectrophotometric method was used to measure level of sodium metabisulphite induced polymerization of deoxyHbS molecule incubated in aqueous extract of N. tabacum for 180 s. The polymerization profile of deoxyHbS molecules of control and test samples showed increasing level of polymerization with progression of experimental time. At experimental time t > 30 s, level of polymerization of control sample ranged between 60.9±0.76 – 100±1.05%, whereas, the test samples ranged in the following corresponding order: [N. tabacum] = 0.8 mg/100 mL, 65.6±0.93 – 176.0±4.26%; [N. tabacum] = 1.0 mg/100 mL, 75.7±1.07 – 192.9±5.03% and [N. tabacum] = 2.0 mg/100 mL, 135.9±5.04 – 297.2±19.14%. Activation of deoxyHbS polymerization by aqueous extract of N. tabacum increased in a concentration dependent manner and duration of incubation. Specifically, at t = 100 s, [N. tabacum] = 2.0 mg/100 mL caused highest level of activation of deoxyHbS polymerization (197.2±19.14%); an increase in %polymerization in a ratio of 1: 4.5 (approx.) compared with [N. tabacum] = 0.8 mg/100 mL at t = 30 s. The study showed that aqueous extract of N. tabacum exacerbated polymerization of deoxyHbS molecules in a concentration and time dependent manner. Therefore, N. tabacum may present experimental form did not exhibit therapeutic potentials for management and alleviation of sickling disorder.

Keywords: Polymerization, sickle cell haemoglobin, N. tabacum, sodium metabisulphite.

INTRODUCTION
The sickle cell gene (β) occurs widely throughout Africa, part of Asia, the Arabian Peninsula and part of Southern Europe. In Africa, there are two areas with very high frequencies of β. One includes Nigeria, Ghana, and the other, Gabon and Zaire [1; 2]. Sickle cell anaemia (SCA) occurs with a much lower incidence in part of Italy, Greece, the Middle East and India. The homozygous state of SCA is associated with complications and a reduced life expectancy [3; 4]. The sickle cell haemoglobin (HbS) variant is caused by a point mutation affecting the coding sequence of the β-globin gene resulting in a substitution of glutamic acid by valine at the sixth position of β-globin chains [3; 5]. Under low oxygen tension, deoxyHbS molecules polymerize into microfibrils parallel to each other with concomitant reduced solubility (forms gel) and resultant erythrocyte membrane deformity and damage [6]. Therapeutic approaches for the treatment and management of SCA disease include induction of fetal hemoglobin expression [5; 7], bone marrow transplantation [8; 9], and the use of pharmacological agents that interact either non-covalently or covalently with HbS molecules [10; 11] to retard or inhibit haemoglobin aggregation and polymerization.

The tobacco plant (Nicotianatabacum) has been used for several years and purposes, irrespective of the location of human races. Cigarettes, in spite of the health risk associated with its usage constitute the largest share of manufactured tobacco products in the world, accounting for 96% of total sales. [12]. The chemical compositions of N. tabacum leaf extract have been previously reported [13-15]. The prospects of utilization of N. tabacum products for purposes that do not pose health risk are now widely encouraged and advertised. [16]. There are reports and claims by several authors on the medicinal benefits [15; 17] and biologic activities, such as ovicidal, repellent, and insecticidal activities against various insect species [18-20] by leaf extracts of N. tabacum. Application of herbal remedies for the management of SCA have been widely reported [21-24]. In vitro studies have revealed that plant extracts altered the polymerization of deoxyHbS molecules [24; 25]. Therefore, the present study seeks to ascertain the capacity of aqueous extract of N. tabacum to alter and interfere with the polymerization of deoxyHbS molecules in vitro.
MATERIALS AND METHODS

Collection and preparation of Nicotianatabacum leaf extract

Preparation of aqueous extract of N. tabacum was according to the methods earlier described by Chikezie and Uwakwe, [26]. Twenty five grams (25 g) of processed leaves of N. tabacum obtained from the popular cigarette brand Benson & Hedges™ were collected in desiccators and allowed to dry for 72 h to become crispy. The dried specimen was ground in ceramic mortar and pestle into fine powder. The pulverized specimen was suspended in 100 mL of distilled water and allowed to stand for 6 h at 37°C. Aqueous extract of N. tabacum was obtained by filtration with Whatman No. 2 filter paper. Finally, the extract was concentrated in a rotary evaporator at 50°C and dried in vacuum desiccators. The yield was calculated to be 5.14% (1.29 g; w/w). The extract was finally suspended in 50 mL phosphate buffered saline (PBS) solution osmotically equivalent to 0.9 g/100 mL NaCl {NaCl (9.0 g), NaH2PO4·2H2O (1.71 g) and NaH2PO4·2H2O (0.243 g)/100 mL; pH = 7.4} [27]. The extract was kept at 4°C in a refrigerator for at least 24 h before subsequent tests. Concentration equivalents of 0.8, 1.0 and 2.0 mg/100 mL aqueous extracts of N. tabacum were used for polymerization studies.

Ethics: The institutional review board of the Department of Biochemistry, Imo State University, Owerri, Nigeria, granted approval for this study and all participants involved signed an informed consent form. This study was in accordance with the ethical principles that have their origins in the Declaration of Helsinki. Individuals drawn were from Imo State University, Owerri and environs. The research protocols were in collaboration with registered and specialized clinics and medical laboratories.

Collection of Blood Samples/Preparation of Erythrocyte Haemolysate:

Five milliliters (5.0 mL) of venous blood obtained from the volunteers by venipuncture was stored in EDTA anticoagulant tubes. Blood samples were from patients attending clinics at the Federal Medical Center (FMC), Imo State University Teaching Hospital (IMSUTH), Orlu, St. John Clinic/Medical Diagnostic Laboratories, Avigram Medical Diagnostic Laboratories, and Qualitech Medical Diagnostic Laboratories. These centers are located in Owerri, Imo State, Nigeria. The erythrocytes were separated from plasma and washed by centrifugation method as described by Tsakiris et al., [28] with minor modification according to Penningset al., [29]. Blood volume of 4.0 mL was introduced into centrifuge test tubes containing 4.0 mL of buffer solution pH = 7.4: 250 mMtris (hydroxyl methyl) amino ethane–HCl (Tris-HCl)/ 140 mMNaCl/ 1.0 mM MgCl2/ 10 mM glucose and centrifuged at 4000 rpm for 10 min using a centrifuge (B.Bran Scientific and Instrument Company, England). The plasma and buffy coat (supernatant) were carefully removed with Pasteur pipette. This process was repeated until the supernatant became clear. The pelleted erythrocytes were suspended in PBS (pH=7.4) to obtain approximately 10% haematocrit and stored at 4°C for 24 h. The washed erythrocytes were lysed by freezing/thawing as described by Galbraith and Watts, [30] and Kamberet al., [31]. The erythrocyte haemolysate was used for polymerization studies.

Polymerization studies

Sodium metabisulfite (Na2S2O5; (BDH, UK))-induced polymerization of HbS molecules was ascertained as described previously by Iwuet al., [32] with minor modification according to Chikezie et al., [33]. The underlying principle is that HbS molecules undergo gelation when deprived of oxygen, transiting to deoxyHbS molecules; Na2S2O5 was used as the reductant. The level of polymerization was measured by recording increasing absorbance of the assay mixture with progression of time. A 0.1 mL of HbS haemolysate was introduced into a test tube, followed by 0.5 mL of PBS and 1.0 mL of distilled water. The mixture was transferred into a cuvette and 3.4 mL of 2 g/100 mL aqueous solution of Na2S2O5 was added. The absorbance (λmax = 700 nm) of the assay mixture was measured with a spectrophotometer (SPECTRONIC 20, Labtech—Digital Blood Analyzer®) at every 30 s for 180 s (control assay). This procedure was repeated by substituting distilled water with 1.0 mL of corresponding three increasing concentrations (0.8, 1.0 and 2.0 mg/100 mL) of N.tabacum aqueous extracts (test assay).

Calculations

Percentage polymerization was calculated according to Chikezie et al. [33], thus;

\[
\%\text{Polymerization} = \frac{A_{t/c,100}}{A_{180th s}}
\]

Where

At/c = Absorbance of test/control assay at time = t s.
A180th s = Absorbance of control assay at the 180th s.

Cumulative polymerization (\% polymerization second) was evaluated using the Simpson’s Rule. Thus:

\[f(X_1)h_1 + f(X_2)h_2 + \ldots + f(X_n)h_n\]
Area under the curve (AUC) of the plot of %polymerization versus time (s) is given by:

\[
AUC(\%\text{polymerization}\cdot \text{second}) = \frac{h}{2} (y_n + 2y_{n-1} + 2y_{n-2} + 2y_{n-3} + \cdots) \tag{Equation 1}
\]

Where

\( h = \) time intervals (30 s).
\( y = \%\text{polymerization} \) at corresponding time interval.

Thus:

\[
AUC(\%\text{polymerization}\cdot \text{second}) = \frac{h}{2} (y_6 + 2y_5 + 2y_4 + 2y_3 + 2y_2 + y_1) \tag{Equation 2}
\]

**RESULTS**

The results illustrated in Figure 1 showed that deoxyHbS molecules of the control and test samples showed increasing level of polymerization with progression of experimental time. At experimental time \( t > 30 \) s, level of polymerization of control sample ranged between 60.9±0.76 – 100±1.05%, whereas, the test samples ranged in the following corresponding order: \([N. \text{tabacum}] = 0.8 \text{mg/100 mL, 65.6±0.93 – 176.0±4.26%}; \ [N. \text{tabacum}] = 1.0 \text{mg/100 mL, 75.7±1.07 – 192.9±5.03% and [N. \text{tabacum}] = 2.0 mg/100 mL, 135.9±5.04 – 297.2±19.14%}. \) Therefore, the three experimental concentrations of \( N. \text{tabacum} \) caused activation of deoxyHbS polymerization in the order: \([N. \text{tabacum}] = 0.8 \text{mg/100 mL < 1.0 mg/100 mL < 2.0 mg/100 mL}. \) Furthermore, cumulative level of deoxyHbS polymerization was in the order: Control < \([N. \text{tabacum}] = 0.8 \text{mg/100 mL < 1.0 mg/100 mL < 2.0 mg/100 mL}. \) (Table 1).

Table 2 showed that activation of deoxyHbS polymerization by aqueous extract of \( N. \text{tabacum} \) increased in a concentration dependent manner and duration of incubation. Specifically, at \( t = 180 \) s, \([N. \text{tabacum}] = 2.0 \text{mg/100 mL} \) caused highest level of activation of deoxyHbS polymerization (197.2±19.14%). The value represented an increase of %polymerization in a ratio of 1: 4.5 (approx.) compared with \([N. \text{tabacum}] = 0.8 \text{mg/100 mL} \) at \( t = 30 \) s.
Table 2: Activation of DeoxyHbS polymerization in the presence aqueous extracts of N. tabacum within intervals of t = 30 s.

The results are means (X) ± SD of six (n = 6) determinations. When t > 30 s, deoxyHbS incubated in aqueous extract [N. tabacum] = 2.0 mg/100 mL exhibited %polymerization> 100%. Likewise, %polymerization> 100% in the presence of 0.8 and 1.0 mg//100 mL of N. tabacum occurred when t > 60 s and t > 30 s respectively.

DISCUSSION

The nature and mode of interaction between biochemical agents and contact points of deoxyHbS molecules, in addition to erythrocyte membrane structural components are crucial determining factors in the capability of these agents to retard/inhibit polymerization of deoxyHbS molecules, to alleviate and prevent erythrocyte sickling disorders [25; 26; 34; 35]. Contrary to reports by previous authors and researchers on the anti-polymerization [24; 25] and claims of anti-sickling potencies [21-24; 35] of plant extracts, the present report showed that aqueous extract of N. tabacumextercerbated polymerization of deoxyHbS molecules. Chitra and Sivarangani, [15] have previously reported that processed N. tabacum(leaf powder) was devoid of flavonoids and terpenoids. These two phytochemicals have been implicated in inhibiting polymerization of deoxyHbS molecules and by extension exhibited anti-sickling activity on human HbSS erythrocytes in vitro [35; 36]. However, it is worthwhile to note that the biologic action of N. tabacum HbS molecules reported here and the capacity plant extracts to alter erythrocytes physiochemical properties is an additive effect of combination of the plant components [37].

Haemoglobin polymerization and subsequent sickling of erythrocytes is favoured when HbS molecules are deoxygenated [38; 39]. In the present in vitro study, the aggravation of polymerization of deoxyHbS molecules by the three experimental concentrations of N. tabacum was an obvious reflection of the capability of the plant extract to act in synergy with the hypoxemic agent (Na₂S₃O₇), thereby facilitating more rapid rate of polymerization of HbS molecules compared with the control assay (Figure 1). Conversely, chemical compounds and phytochemicals that serve to stabilize the R-state of HbS molecules with resulting increase oxygen/haemoglobin affinity will cause reduction in the rate and degree of HbS polymerization [25; 34]. Aqueous extracts of N. tabacum the present experimental form did not demonstrate R-state stabilizing property in vitro and therefore, did not exhibit therapeutic potentials for the management and alleviation of sickling disorder.
